Introduction

Calculus is the mathematical study of continuous change established by Issac Newton and Gottfried Wilhelm Leibniz. **Single variable calculus** studies **derivatives** and **integrals** of functions of one variable and their relationship stated by the **fundamental theorem of calculus**.

$$\int_a^b f(x) dx = F(b) - F(a)$$

1 Functions and Limits

1.1 The Limit of a Function

Functions

Definition 1.1.1. A **function** f is a rule that assigns to each element x in a set D exactly one element $f(x)$ in a set E .

Definition 1.1.2. A function f is **injective** (or **one-to-one**) if $f(x_1) \neq f(x_2)$ when $x_1 \neq x_2$.

Definition 1.1.3. A function f is **surjective** (or **onto**) if for all y in range Y , there exists an x in domain X such that $f(x) = y$.

Definition 1.1.4. A function f is **bijective** if f is injective and surjective.

Definition 1.1.5. Let f be a one-to-one function with domain A and range B . Then its **inverse function** f^{-1} has domain B and range A and is defined by

$$f^{-1}(y) = x \iff f(x) = y$$

for all y in B .

Intuitive Definition of a Limit

Suppose $f(x)$ is defined near the number a . (This means that $f(x)$ is defined on some open interval that contains the number a , except possibly at a itself.)

Definition 1.1.6. We write

$$\lim_{x \rightarrow a} f(x) = L$$

and say that the **limit** of $f(x)$, as x approaches a , equals L , if we can make the values of $f(x)$ arbitrarily close to L by taking x to be sufficiently close to a but $x \neq a$.

An alternative notation for the limit is $f(x) \rightarrow L$ as $x \rightarrow a$.

One-Sided Limits

Definition 1.1.7. We write

$$\lim_{x \rightarrow a^-} f(x) = L$$

and say that the **left-hand limit** of $f(x)$ as x approaches a is equal to L if we can make the values of $f(x)$ arbitrarily close to L by taking x sufficiently close to a and $x < a$.

Definition 1.1.8. We write

$$\lim_{x \rightarrow a^+} f(x) = L$$

and say that the **right-hand limit** of $f(x)$ as x approaches a is equal to L if we can make the values of $f(x)$ arbitrarily close to L by taking x sufficiently close to a and $x > a$.

Theorem 1.1.1. $\lim_{x \rightarrow a} f(x) = L$ if and only if $\lim_{x \rightarrow a^-} f(x) = L$ and $\lim_{x \rightarrow a^+} f(x) = L$.

The limit exists if and only if the left-hand limit and the right-hand limit of $f(x)$ as x approaches a are equal to L , otherwise the limit does not exist.

1.2 The Precise Definition of a Limit

Precise Definition of a Limit

Let f be a function defined on some open interval that contains the number a , except possibly at a itself.

Definition 1.2.1. We say that limit of $f(x)$ as x approaches a is L , and we write

$$\lim_{x \rightarrow a} f(x) = L$$

if for every number $\varepsilon > 0$ there is a corresponding number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |f(x) - L| < \varepsilon$$

Problem 1.2.1. Prove that $\lim_{x \rightarrow 3} (4x - 5) = 7$.

Solution. Let $\varepsilon > 0$ be a given positive number. We want to find a number δ such that

$$0 < |x - 3| < \delta \implies |(4x - 5) - 7| < \varepsilon$$

But $|(4x - 5) - 7| = |4x - 12| = 4|x - 3|$. Note that $4|x - 3| < \varepsilon \iff |x - 3| < \varepsilon/4$. Let $\delta = \varepsilon/4$, we have

$$0 < |x - 3| < \frac{\varepsilon}{4} \implies 4|x - 3| < \varepsilon \implies |(4x - 5) - 7| < \varepsilon$$

Therefore, by the definition of a limit,

$$\lim_{x \rightarrow 3} (4x - 5) = 7$$

■

Problem 1.2.2. Prove that $\lim_{x \rightarrow 3} x^2 = 9$.

Solution. Let ε be a given positive number. We want to find a number δ such that

$$0 < |x - 3| < \delta \implies |x^2 - 9| < \varepsilon$$

We simplify to get

$$|x^2 - 9| = |x + 3| |x - 3| < \varepsilon$$

Let C be a positive constant such that

$$|x + 3| |x - 3| < C |x - 3| < \varepsilon \iff |x - 3| < \frac{\varepsilon}{C}$$

Since we are interested only in values of x that are close to 3, it is reasonable to assume that $|x - 3| < 1$. Then we have $|x + 3| < 7$, and so $C = 7$. Let $\delta = \min\{1, \varepsilon/7\}$. If $0 < |x - 3| < \delta$, then

$$|x^2 - 9| = |x + 3| |x - 3| < 7 \cdot \frac{\varepsilon}{7} = \varepsilon$$

This shows that $\lim_{x \rightarrow 3} x^2 = 9$.

■

Definition 1.2.2.

$$\lim_{x \rightarrow a^-} f(x) = L$$

if for every number $\varepsilon > 0$ there is a number $\delta > 0$ such that

$$a - \delta < x < a \implies |f(x) - L| < \varepsilon$$

Definition 1.2.3.

$$\lim_{x \rightarrow a^+} f(x) = L$$

if for every number $\varepsilon > 0$ there is a number $\delta > 0$ such that

$$a < x < a + \delta \implies |f(x) - L| < \varepsilon$$

Problem 1.2.3. Prove that $\lim_{x \rightarrow 0^+} \sqrt{x} = 0$.

Solution. Let ε be a given positive number. We want to find a number δ such that

$$0 < x < \delta \implies |\sqrt{x} - 0| < \varepsilon$$

But $\sqrt{x} < \varepsilon \iff x < \varepsilon^2$. Let $\delta = \varepsilon^2$. If $0 < x < \delta$, then $\sqrt{x} < \sqrt{\delta} = \sqrt{\varepsilon^2} = \varepsilon$ so $|\sqrt{x} - 0| < \varepsilon$. This shows that $\lim_{x \rightarrow 0^+} \sqrt{x} = 0$. ■

1.3 Calculating Limits Using the Limit Laws

We have the following properties of limits called the **limit laws** to calculate limits. Suppose that c is a constant and the limits

$$\lim_{x \rightarrow a} f(x) = L$$

$$\lim_{x \rightarrow a} g(x) = M$$

exist. Then

$$1. \text{ Sum Law: } \lim_{x \rightarrow a} [f(x) + g(x)] = L + M$$

$$2. \text{ Difference Law: } \lim_{x \rightarrow a} [f(x) - g(x)] = L - M$$

$$3. \text{ Constant Multiple Law: } \lim_{x \rightarrow a} [cf(x)] = cL$$

$$4. \text{ Product Law: } \lim_{x \rightarrow a} [f(x)g(x)] = LM$$

$$5. \text{ Quotient Law: } \lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \frac{L}{M} \text{ if } M \neq 0.$$

$$6. \text{ Power Law: } \lim_{x \rightarrow a} [f(x)]^n = \left[\lim_{x \rightarrow a} f(x) \right]^n \text{ where } n \text{ is a positive integer.}$$

$$7. \text{ Root Law: } \lim_{x \rightarrow a} \sqrt[n]{f(x)} = \sqrt[n]{\lim_{x \rightarrow a} f(x)} \text{ where } n \text{ is a positive integer. If } n \text{ is even, we assume that } \lim_{x \rightarrow a} f(x) > 0.$$

8. $\lim_{x \rightarrow a} c = c$

9. $\lim_{x \rightarrow a} x = a$

10. $\lim_{x \rightarrow a} x^n = a^n$ where n is a positive integer.

11. $\lim_{x \rightarrow a} \sqrt[n]{x} = \sqrt[n]{a}$ where n is a positive integer. If n is even, we assume that $a > 0$.

Proof. Proof of limit law 8: Let $\varepsilon > 0$ be given, we want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |c - c| < \varepsilon$$

We have $|c - c| = 0 < \varepsilon$ so the trivial inequality is always true for any number $\delta > 0$. It is proved that $\lim_{x \rightarrow a} c = c$. ■

Proof. Proof of limit law 9: Let $\varepsilon > 0$ be given, we want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |x - a| < \varepsilon$$

Let $\delta = \varepsilon$, we have

$$0 < |x - a| < \delta = \varepsilon \implies |x - a| < \varepsilon$$

It is proved that $\lim_{x \rightarrow a} x = a$. ■

Proof. Proof of the sum law: Let $\varepsilon > 0$ be given, we want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |f(x) + g(x) - (L + M)| < \varepsilon$$

By the triangle inequality,

$$|f(x) + g(x) - (L + M)| = |f(x) - L + g(x) - M| \leq |f(x) - L| + |g(x) - M|$$

We make $|f(x) - L| + |g(x) - M|$ less than ε by making each of the terms $|f(x) - L|$ and $|g(x) - M|$ less than $\varepsilon/2$. Since $\lim_{x \rightarrow a} f(x) = L$, there is a number $\delta_1 > 0$ such that

$$0 < |x - a| < \delta_1 \implies |f(x) - L| < \frac{\varepsilon}{2}$$

Similarly, there is a number $\delta_2 > 0$ such that

$$0 < |x - a| < \delta_2 \implies |g(x) - M| < \frac{\varepsilon}{2}$$

Let $\delta = \min\{\delta_1, \delta_2\}$. If $0 < |x - a| < \delta$, then $0 < |x - a| < \delta_1$ and $0 < |x - a| < \delta_2$ and so

$$|f(x) - L| + |g(x) - M| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon$$

Then

$$0 < |x - a| < \delta \implies |f(x) + g(x) - (L + M)| < \varepsilon$$

Thus, by the definition of a limit,

$$\lim_{x \rightarrow a} [f(x) + g(x)] = L + M$$

■

Proof. Proof of the product law: Let $\varepsilon > 0$ be given, we want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |f(x)g(x) - LM| < \varepsilon$$

In order to get terms that contain $|f(x) - L|$ and $|g(x) - M|$, we add and subtract $Lg(x)$ as follows and use the triangle inequality:

$$\begin{aligned} |f(x)g(x) - LM| &= |f(x)g(x) - Lg(x) + Lg(x) - LM| \\ &= \left| [f(x) - L]g(x) + L[g(x) - M] \right| \\ &\leq \left| [f(x) - L]g(x) \right| + \left| L[g(x) - M] \right| \\ &= |f(x) - L| |g(x)| + |L| |g(x) - M| \end{aligned}$$

We want to make both of the terms less than $\varepsilon/2$. Since $\lim_{x \rightarrow a} g(x) = M$, there is a number $\delta_1 > 0$ such that

$$0 < |x - a| < \delta_1 \implies |g(x) - M| < \frac{\varepsilon}{2(1 + |L|)}$$

Also, there is a number $\delta_2 > 0$ such that

$$0 < |x - a| < \delta_2 \implies |g(x) - M| < 1$$

and therefore

$$|g(x)| = |g(x) - M + M| \leq |g(x) - M| + |M| < 1 + |M|$$

Since $\lim_{x \rightarrow a} f(x) = L$, there is a number $\delta_3 > 0$ such that

$$0 < |x - a| < \delta_3 \implies |f(x) - L| < \frac{\varepsilon}{2(1 + |M|)}$$

Let $\delta = \min\{\delta_1, \delta_2, \delta_3\}$. If $0 < |x - a| < \delta$, then $0 < |x - a| < \delta_1$, $0 < |x - a| < \delta_2$, and $0 < |x - a| < \delta_3$. Then we can combine the inequalities to get

$$\begin{aligned} |f(x)g(x) - LM| &\leq |f(x) - L| |g(x)| + |L| |g(x) - M| \\ &< \frac{\varepsilon}{2(1 + |M|)} (1 + |M|) + |L| \frac{\varepsilon}{2(1 + |L|)} \\ &< \frac{\varepsilon}{2(1 + |M|)} (1 + |M|) + (1 + |L|) \frac{\varepsilon}{2(1 + |L|)} \\ &= \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon \end{aligned}$$

This shows that

$$\lim_{x \rightarrow a} [f(x)g(x)] = LM$$

■

Proof. Proof of the constant multiple law: If we take $g(x) = c$ then by the product law and limit law 8, we get

$$\lim_{x \rightarrow a} [cf(x)] = \lim_{x \rightarrow a} c \cdot \lim_{x \rightarrow a} f(x) = c \lim_{x \rightarrow a} f(x) = cL$$

We can prove the constant multiple law using the precise definition. Note that if $c = 0$, then $cf(x) = 0$ and we have

$$\lim_{x \rightarrow a} [0 \cdot f(x)] = \lim_{x \rightarrow a} 0 = 0 = 0 \cdot \lim_{x \rightarrow a} f(x) = 0 \cdot L$$

Let $\varepsilon > 0$ and $c \neq 0$ be given, we want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |cf(x) - cL| < \varepsilon$$

We simplify to get

$$|f(x) - L| < \frac{\varepsilon}{|c|}$$

By the definition of a limit, there is a number $\delta_1 > 0$ such that

$$0 < |x - a| < \delta_1 \implies |f(x) - L| < \frac{\varepsilon}{|c|}$$

Let $\delta = \delta_1$, we have

$$0 < |x - a| < \delta \implies |cf(x) - cL| < \varepsilon$$

This shows that $\lim_{x \rightarrow a} [cf(x)] = cL$. ■

Proof. Proof of the difference law: Using the sum law and the constant multiple law with $c = -1$, we have

$$\begin{aligned} \lim_{x \rightarrow a} [f(x) - g(x)] &= \lim_{x \rightarrow a} [f(x) + (-1)g(x)] = \lim_{x \rightarrow a} f(x) + \lim_{x \rightarrow a} (-1)g(x) \\ &= \lim_{x \rightarrow a} f(x) + (-1) \lim_{x \rightarrow a} g(x) = \lim_{x \rightarrow a} f(x) - \lim_{x \rightarrow a} g(x) = L - M \end{aligned}$$
■

Proof. Proof of the quotient law: First we prove that

$$\lim_{x \rightarrow a} \frac{1}{g(x)} = \frac{1}{M}$$

Let $\varepsilon > 0$ be given, we want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies \left| \frac{1}{g(x)} - \frac{1}{M} \right| < \varepsilon$$

Observe that

$$\left| \frac{1}{g(x)} - \frac{1}{M} \right| = \frac{|M - g(x)|}{|Mg(x)|} = \frac{|g(x) - M|}{|Mg(x)|}$$

Since $\lim_{x \rightarrow a} g(x) = M$, there is a number δ_1 such that

$$0 < |x - a| < \delta_1 \implies |g(x) - M| < \frac{|M|}{2}$$

and therefore

$$|M| = |M - g(x) + g(x)| \leq |M - g(x)| + |g(x)| = |g(x) - M| + |g(x)| < \frac{|M|}{2} + |g(x)|$$

This shows that

$$0 < |x - a| < \delta_1 \implies \frac{|M|}{2} < |g(x)| \iff \frac{1}{|g(x)|} < \frac{2}{|M|}$$

and so, for these values of x ,

$$\frac{1}{|Mg(x)|} = \frac{1}{|M| |g(x)|} < \frac{1}{|M|} \cdot \frac{2}{|M|} = \frac{2}{M^2}$$

Also, there is a number $\delta_2 > 0$ such that

$$0 < |x - a| < \delta_2 \implies |g(x) - M| < \frac{M^2}{2} \varepsilon$$

Let $\delta = \min\{\delta_1, \delta_2\}$. If $0 < |x - a| < \delta$, then

$$\left| \frac{1}{g(x)} - \frac{1}{M} \right| = \frac{|M - g(x)|}{|Mg(x)|} = \frac{1}{|Mg(x)|} |g(x) - M| < \frac{2}{M^2} \frac{M^2}{2} \varepsilon = \varepsilon$$

which is what we want to show. We apply the product law to prove the quotient law

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \left(f(x) \cdot \frac{1}{g(x)} \right) = \lim_{x \rightarrow a} f(x) \lim_{x \rightarrow a} \frac{1}{g(x)} = L \cdot \frac{1}{M} = \frac{L}{M}$$

■

We have the following **direct substitution property** to calculate limits. If f is a polynomial or a rational function and a is in the domain of f , then

$$\lim_{x \rightarrow a} f(x) = f(a)$$

Problem 1.3.1. Find $\lim_{x \rightarrow 1} \frac{x^2 - 1}{x - 1}$.

Solution.

$$\lim_{x \rightarrow 1} \frac{x^2 - 1}{x - 1} = \lim_{x \rightarrow 1} \frac{(x + 1)(x - 1)}{x - 1} = \lim_{x \rightarrow 1} (x + 1) = 1 + 1 = 2$$

■

If $f(x) = g(x)$ when $x \neq a$, then $\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} g(x)$, provided that this limit exists. When computing one-sided limits, we use the fact that the limit laws also hold for one-sided limits.

Problem 1.3.2. Show that $\lim_{x \rightarrow 0} |x| = 0$.

Solution. Since $|x| = x$ for $x > 0$, we have

$$\lim_{x \rightarrow 0^+} |x| = \lim_{x \rightarrow 0^+} x = 0$$

For $x < 0$ we have $|x| = -x$ so

$$\lim_{x \rightarrow 0^-} |x| = \lim_{x \rightarrow 0^-} (-x) = 0$$

Therefore, it is shown that $\lim_{x \rightarrow 0} |x| = 0$. ■

The Squeeze Theorem

Theorem 1.3.1. If $f(x) \leq g(x)$ for all x in an open interval that contains a (except possibly at a) and

$$\lim_{x \rightarrow a} f(x) = L \qquad \lim_{x \rightarrow a} g(x) = M$$

then $L \leq M$.

Proof. We use the method of proof by contradiction. Suppose that $L > M$, then we have

$$\lim_{x \rightarrow a} [g(x) - f(x)] = M - L$$

Therefore, for any number $\varepsilon > 0$, there is a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies \left| [g(x) - f(x)] - (M - L) \right| < \varepsilon$$

Note that $L - M > 0$ by the hypothesis. Let $\varepsilon = L - M$, there is a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies \left| [g(x) - f(x)] - (M - L) \right| < L - M$$

Since $a \leq |a|$ for any number a , we have

$$0 < |x - a| < \delta \implies [g(x) - f(x)] - (M - L) < L - M$$

which simplifies to

$$0 < |x - a| < \delta \implies g(x) < f(x)$$

But this contradicts $f(x) \leq g(x)$. Thus the inequality $L > M$ must be false. Therefore $L \leq M$. ■

Theorem 1.3.2 Squeeze Theorem. If $f(x) \leq g(x) \leq h(x)$ for all x in an open interval that contains a (except possibly at a) and

$$\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} h(x) = L$$

then

$$\lim_{x \rightarrow a} g(x) = L$$

Proof. Let $\varepsilon > 0$ be given. Since $\lim_{x \rightarrow a} f(x) = L$, there is a number $\delta_1 > 0$ such that

$$0 < |x - a| < \delta_1 \implies |f(x) - L| < \varepsilon \implies L - \varepsilon < f(x) < L + \varepsilon$$

Since $\lim_{x \rightarrow a} h(x) = L$, there is a number $\delta_2 > 0$ such that

$$0 < |x - a| < \delta_2 \implies |h(x) - L| < \varepsilon \implies L - \varepsilon < h(x) < L + \varepsilon$$

Let $\delta = \min\{\delta_1, \delta_2\}$. If $0 < |x - a| < \delta$, then $0 < |x - a| < \delta_1$ and $0 < |x - a| < \delta_2$, so

$$L - \varepsilon < f(x) \leq g(x) \leq h(x) < L + \varepsilon$$

In particular,

$$L - \varepsilon < g(x) < L + \varepsilon$$

and so $|g(x) - L| < \varepsilon$. Therefore $\lim_{x \rightarrow a} g(x) = L$. ■

Problem 1.3.3. Show that $\lim_{x \rightarrow 0} x^2 \sin \frac{1}{x} = 0$.

Solution. Since

$$-1 \leq \sin \frac{1}{x} \leq 1$$

then

$$-x^2 \leq x^2 \sin \frac{1}{x} \leq x^2$$

We know that

$$\lim_{x \rightarrow 0} (-x^2) = 0$$

$$\lim_{x \rightarrow 0} x^2 = 0$$

By the squeeze theorem,

$$\lim_{x \rightarrow 0} x^2 \sin \frac{1}{x} = 0$$
■

If $0 < \theta < \pi/2$, then

$$\sin \theta < \theta \implies \frac{\sin \theta}{\theta} < 1$$

and $\theta \leq \tan \theta$. Therefore we have

$$\theta < \tan \theta = \frac{\sin \theta}{\cos \theta} \implies \cos \theta < \frac{\sin \theta}{\theta} < 1$$

We know that $\lim_{\theta \rightarrow 0} 1 = 1$ and $\lim_{\theta \rightarrow 0} \cos \theta = 1$, so by the squeeze theorem, we have

$$\lim_{\theta \rightarrow 0^+} \frac{\sin \theta}{\theta} = 1$$

But the function $(\sin \theta)/\theta$ is an even function, so its left and right limits must be equal. Hence we have

$$\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1$$

Problem 1.3.4. Find $\lim_{x \rightarrow 0} \frac{\sin 7x}{4x}$.

Solution.

$$\lim_{x \rightarrow 0} \frac{\sin 7x}{4x} = \lim_{x \rightarrow 0} \frac{7x \cdot \sin 7x}{4x \cdot 7x} = \frac{7}{4} \lim_{x \rightarrow 0} \frac{\sin 7x}{7x} = \frac{7}{4}$$

■

Problem 1.3.5. Evaluate $\lim_{\theta \rightarrow 0} \frac{\cos \theta - 1}{\theta}$.

Solution. We have

$$\frac{\cos \theta - 1}{\theta} = \frac{\cos \theta - 1}{\theta} \left(\frac{\cos \theta + 1}{\cos \theta + 1} \right) = \frac{\cos^2 \theta - 1}{\theta(\cos \theta + 1)} = \frac{-\sin^2 \theta}{\theta(\cos \theta + 1)} = \frac{\sin \theta}{\theta} \left(\frac{-\sin \theta}{\cos \theta + 1} \right)$$

We take the limit then

$$\begin{aligned} \lim_{\theta \rightarrow 0} \frac{\cos \theta - 1}{\theta} &= \lim_{\theta \rightarrow 0} \left(\frac{\cos \theta - 1}{\theta} \cdot \frac{\cos \theta + 1}{\cos \theta + 1} \right) = \lim_{\theta \rightarrow 0} \frac{\cos^2 \theta - 1}{\theta(\cos \theta + 1)} = \lim_{\theta \rightarrow 0} \frac{-\sin^2 \theta}{\theta(\cos \theta + 1)} \\ &= -\lim_{\theta \rightarrow 0} \left(\frac{\sin \theta}{\theta} \cdot \frac{\sin \theta}{\cos \theta + 1} \right) = -\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \cdot \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\cos \theta + 1} = -1 \cdot \frac{0}{1 + 1} = 0 \end{aligned}$$

■

1.4 Continuity

Definition 1.4.1. A function f is **continuous at a number a** if

$$\lim_{x \rightarrow a} f(x) = f(a)$$

Note that f is continuous at a requires that $f(a)$ is defined and the limit exists. We say that f is **discontinuous at a** if f is not continuous at a .

Definition 1.4.2. A function f is **continuous from the right at a number a** if

$$\lim_{x \rightarrow a^+} f(x) = f(a)$$

and f is **continuous from the left at a** if

$$\lim_{x \rightarrow a^-} f(x) = f(a)$$

Definition 1.4.3. A function f is **continuous on an interval** if it is continuous at every number in the interval.

Theorem 1.4.1. If f and g are continuous at a and c is a constant, then the following functions are also continuous at a :

1. $f + g$
2. $f - g$
3. cf
4. fg
5. $\frac{f}{g}$ if $g(a) \neq 0$.

Proof. Each of the five parts of this theorem follows from the corresponding limit law. We give the proof of part 1. Since f and g are continuous at a , we have

$$\lim_{x \rightarrow a} f(x) = f(a) \qquad \lim_{x \rightarrow a} g(x) = g(a)$$

Then

$$\lim_{x \rightarrow a} (f + g)(x) = \lim_{x \rightarrow a} [f(x) + g(x)] = \lim_{x \rightarrow a} f(x) + \lim_{x \rightarrow a} g(x) = f(a) + g(a) = (f + g)(a)$$

This shows that $f + g$ is continuous at a . ■

Theorem 1.4.2. Any polynomial is continuous on $\mathbb{R} = (-\infty, \infty)$. Any rational function is continuous on its domain.

Proof. A polynomial is a function of the form

$$P(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_2 x^2 + a_1 x + a_0$$

where the coefficients a_0, a_1, \dots, a_n are constants. $P(x)$ is the sum of power functions with a constant multiple and therefore it is continuous. A rational function is a function of the form

$$f(x) = \frac{P(x)}{Q(x)}$$

where P and Q are polynomials. The domain of f is $D = \{x \in \mathbb{R} \mid Q(x) \neq 0\}$. We know that polynomials are continuous on \mathbb{R} so the rational function f is continuous at every number in D . ■

Theorem 1.4.3. The following types of functions are continuous at every number in their domains:

- Polynomials
- Rational functions

- Root functions
- Trigonometric functions
- Inverse trigonometric functions
- Exponential functions
- Logarithmic functions

Theorem 1.4.4. If f is continuous at b and $\lim_{x \rightarrow a} g(x) = b$, then

$$\lim_{x \rightarrow a} f(g(x)) = f(b)$$

Proof. Let $\varepsilon > 0$ be given. We want to find a number $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |f(g(x)) - f(b)| < \varepsilon$$

Since f is continuous at b , we have

$$\lim_{y \rightarrow b} f(y) = f(b)$$

and so there exists $\delta_1 > 0$ such that

$$0 < |y - b| < \delta_1 \implies |f(y) - f(b)| < \varepsilon$$

Since $\lim_{x \rightarrow a} g(x) = b$, there exists $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |g(x) - b| < \delta_1$$

Combining these two statements, we see that when $0 < |x - a| < \delta$ we have $|g(x) - b| < \delta_1$, which implies that $|f(g(x)) - f(b)| < \varepsilon$. Therefore we have proved that $\lim_{x \rightarrow a} f(g(x)) = f(b)$. ■

Theorem 1.4.5. If g is continuous at a and f is continuous at $g(a)$, then the composite function $f \circ g$ given by $f \circ g = f(g(x))$ is continuous at a .

Proof. Since g is continuous at a , we have

$$\lim_{x \rightarrow a} g(x) = g(a)$$

Since f is continuous at $b = g(a)$, we have

$$\lim_{x \rightarrow a} f(g(x)) = f(g(a))$$

which is precisely the statement that the function $f(g(x))$ is continuous at a . ■

Theorem 1.4.6 Intermediate Value Theorem. Suppose that f is continuous on the closed interval $[a, b]$ and let N be any number between $f(a)$ and $f(b)$, where $f(a) \neq f(b)$. Then there exists a number c in the open interval (a, b) such that $f(c) = N$.

The intermediate value theorem states that a continuous function takes on every intermediate value between the function values $f(a)$ and $f(b)$. If a continuous function $f(x)$ has values of opposite sign in an interval (a, b) , then by the intermediate value theorem there exists a root of $f(x)$ in (a, b) .

1.5 Limits Involving Infinity

Infinite Limits

Definition 1.5.1. The notation

$$\lim_{x \rightarrow a} f(x) = \infty$$

means that the values of $f(x)$ can be made arbitrarily large by taking x sufficiently close to a but $x \neq a$.

Another notation for the limit is $f(x) \rightarrow \infty$ as $x \rightarrow a$. We say that the limit of $f(x)$, as x approaches a , is infinity.

Definition 1.5.2.

$$\lim_{x \rightarrow a} f(x) = -\infty$$

means that the values of $f(x)$ can be made arbitrarily large negative by taking x sufficiently close to a but $x \neq a$.

We say that the limit of $f(x)$, as x approaches a , is negative infinity. Similar definitions can be given for the one-sided infinite limits

$$\begin{array}{ll} \lim_{x \rightarrow a^-} f(x) = \infty & \lim_{x \rightarrow a^+} f(x) = \infty \\ \lim_{x \rightarrow a^-} f(x) = -\infty & \lim_{x \rightarrow a^+} f(x) = -\infty \end{array}$$

Definition 1.5.3. The vertical line $x = a$ is called a **vertical asymptote** of the curve $y = f(x)$ if at least one of the following statements is true:

$$\begin{array}{lll} \lim_{x \rightarrow a} f(x) = \infty & \lim_{x \rightarrow a^-} f(x) = \infty & \lim_{x \rightarrow a^+} f(x) = \infty \\ \lim_{x \rightarrow a} f(x) = -\infty & \lim_{x \rightarrow a^-} f(x) = -\infty & \lim_{x \rightarrow a^+} f(x) = -\infty \end{array}$$

Limits at Infinity

Definition 1.5.4. Let f be a function defined on some interval (a, ∞) . Then

$$\lim_{x \rightarrow \infty} f(x) = L$$

means that the values of $f(x)$ can be made arbitrarily close to L by requiring x to be sufficiently large.

Another notation is $f(x) \rightarrow L$ as $x \rightarrow \infty$. We say that the limit of $f(x)$, as x approaches infinity, is L .

Definition 1.5.5. Let f be a function defined on some interval $(-\infty, a)$. Then

$$\lim_{x \rightarrow -\infty} f(x) = L$$

means that the values of $f(x)$ can be made arbitrarily close to L by requiring x to be sufficiently large negative.

We say that the limit of $f(x)$, as x approaches negative infinity, is L .

Definition 1.5.6. The line $y = L$ is called a **horizontal asymptote** of the curve $y = f(x)$ if either

$$\lim_{x \rightarrow \infty} f(x) = L$$

or

$$\lim_{x \rightarrow -\infty} f(x) = L$$

If n is a positive integer, then

$$\lim_{x \rightarrow \infty} \frac{1}{x^n} = 0$$

$$\lim_{x \rightarrow -\infty} \frac{1}{x^n} = 0$$

Problem 1.5.1. Evaluate $\lim_{x \rightarrow \infty} \sin x$.

Solution. As x increases, the values of $\sin x$ oscillate between 1 and -1 infinitely often. Thus $\lim_{x \rightarrow \infty} \sin x$ does not exist. ■

Infinite Limits at Infinity

The notation

$$\lim_{x \rightarrow \infty} f(x) = \infty$$

is used to indicate that the values of $f(x)$ become large as x becomes large. Similar meanings are attached to the following symbols:

$$\lim_{x \rightarrow \infty} f(x) = \infty$$

$$\lim_{x \rightarrow \infty} f(x) = -\infty$$

$$\lim_{x \rightarrow -\infty} f(x) = -\infty$$

Precise Definitions

Let f be a function defined on some open interval that contains the number a , except possibly at a itself.

Definition 1.5.7.

$$\lim_{x \rightarrow a} f(x) = \infty$$

means that for every positive number M there is a positive number δ such that

$$0 < |x - a| < \delta \implies f(x) > M$$

Problem 1.5.2. Prove that $\lim_{x \rightarrow 0} \frac{1}{x^2} = \infty$.

Solution. Let M be a given positive number. We want to find a number δ such that

$$0 < |x| < \delta \implies \frac{1}{x^2} > M$$

But

$$\frac{1}{x^2} > M \iff x^2 < \frac{1}{M} \iff \sqrt{x^2} < \sqrt{\frac{1}{M}} \iff |x| < \frac{1}{\sqrt{M}}$$

Let $\delta = 1/\sqrt{M}$, then

$$0 < |x| < \delta = \frac{1}{\sqrt{M}} \implies \frac{1}{x^2} > M$$

This shows that $\lim_{x \rightarrow 0} \frac{1}{x^2} = \infty$. ■

Definition 1.5.8.

$$\lim_{x \rightarrow a} f(x) = -\infty$$

if for every negative number N there is a positive number δ such that

$$0 < |x - a| < \delta \implies f(x) < N$$

Definition 1.5.9. Let f be a function defined on some interval (a, ∞) . Then

$$\lim_{x \rightarrow \infty} f(x) = L$$

means that for every $\varepsilon > 0$ there is a corresponding number N such that

$$x > N \implies |f(x) - L| < \varepsilon$$

Definition 1.5.10. Let f be a function defined on some interval $(-\infty, a)$. Then

$$\lim_{x \rightarrow -\infty} f(x) = L$$

means that for every $\varepsilon > 0$ there is a corresponding number N such that

$$x < N \implies |f(x) - L| < \varepsilon$$

Problem 1.5.3. Prove that $\lim_{x \rightarrow \infty} \frac{1}{x} = 0$.

Solution. Given $\varepsilon > 0$, we want to find an N such that

$$x > N \implies \left| \frac{1}{x} - 0 \right| < \varepsilon$$

Since $x \rightarrow \infty$, we can that $x > 0$ in computing the limit. Then $1/x < \varepsilon \iff x > 1/\varepsilon$. Let $N = 1/\varepsilon$, so

$$x > N = \frac{1}{\varepsilon} \implies \left| \frac{1}{x} - 0 \right| = \frac{1}{x} < \varepsilon$$

Therefore, by definition,

$$\lim_{x \rightarrow \infty} \frac{1}{x} = 0$$
■

Definition 1.5.11. Let f be a function defined on some interval (a, ∞) . Then

$$\lim_{x \rightarrow \infty} f(x) = \infty$$

means that for every positive number M there is a corresponding positive number N such that

$$x > N \implies f(x) > M$$

Similar definitions apply when the symbol ∞ is replaced by $-\infty$.

2 Derivatives

2.1 Derivatives and Rates of Change

Tangents

Definition 2.1.1. The **tangent line** of the curve $y = f(x)$ at the point $P(a, f(a))$ is the line through P with slope

$$m = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}$$

provided that this limit exists.

If $h = x - a$, then

$$m = \lim_{h \rightarrow 0} \frac{f(a + h) - f(a)}{h}$$

Let $s = f(t)$ be a **position function** that describes the motion of an object where s is the displacement of the object from the origin at time t . In the time interval from $t = a$ to $t = a + h$ the change in position is $f(a + h) - f(a)$. The average velocity over this time interval is

$$\text{average velocity} = \frac{\text{displacement}}{\text{time}} = \frac{f(a + h) - f(a)}{h}$$

The **velocity** (or **instantaneous velocity**) of the object at time $t = a$ is the limit of the average velocities:

$$v(a) = \lim_{h \rightarrow 0} \frac{f(a + h) - f(a)}{h}$$

Derivatives

Definition 2.1.2. The **derivative of a function f at a number a** is

$$f'(a) = \lim_{h \rightarrow 0} \frac{f(a + h) - f(a)}{h}$$

if this limit exists.

The tangent line to $y = f(x)$ at the point $(a, f(a))$ is the line through $(a, f(a))$ whose slope is equal to $f'(a)$, the derivative of f at a . The equation of the tangent line in point-slope form is

$$y - f(a) = f'(a)(x - a)$$

Rates of Change

Suppose y is a quantity that depends on another quantity x . Thus y is a function of x and we write $y = f(x)$. If x changes from x_1 to x_2 , then the change in x (also called the **increment** of x) is

$$\Delta x = x_2 - x_1$$

and the corresponding change in y is

$$\Delta y = f(x_2) - f(x_1)$$

The difference quotient

$$\frac{\Delta y}{\Delta x} = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$$

is called the **average rate of change of y with respect to x** over the interval $[x_1, x_2]$. The limit of these average rates of change is called the **(instantaneous) rate of change of y with respect to x** at $x = x_1$:

$$\text{instantaneous rate of change} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \lim_{x_1 \rightarrow x_2} \frac{f(x_2) - f(x_1)}{x_2 - x_1}$$

We recognize this limit as being the derivative $f'(x_1)$. The derivative $f'(a)$ is the instantaneous rate of change of $y = f(x)$ with respect to x when $x = a$. If $s = f(t)$ is a position function of a particle, then $f'(a)$ is the rate of change of the displacement s with respect to time t . $f'(a)$ is the velocity of the particle at time $t = a$. The **speed** of the particle is $|f'(a)|$, the absolute value of the velocity.

2.2 The Derivative as a Function

Definition 2.2.1. The **derivative of a function f** is the function

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

Problem 2.2.1. Find the derivative of $f(x) = \sqrt{x}$.

Solution.

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{\sqrt{x+h} - \sqrt{x}}{h} = \lim_{h \rightarrow 0} \left(\frac{\sqrt{x+h} - \sqrt{x}}{h} \cdot \frac{\sqrt{x+h} + \sqrt{x}}{\sqrt{x+h} + \sqrt{x}} \right) \\ &= \lim_{h \rightarrow 0} \frac{x+h-x}{h(\sqrt{x+h} + \sqrt{x})} = \lim_{h \rightarrow 0} \frac{1}{\sqrt{x+h} + \sqrt{x}} = \frac{1}{\sqrt{x} + \sqrt{x}} = \frac{1}{2\sqrt{x}} \end{aligned}$$

■

Notations

The following notations for the derivative of the function $y = f(x)$ with respect to x are equivalent:

$$y' = f'(x) = \frac{dy}{dx} = \frac{d}{dx} f(x) = D_x f(x)$$

The symbols d/dx and D_x are called **differential operators** because they indicate the operation of **differentiation**, which is the process of calculating a derivative. The symbol dy/dx is called the Leibniz notation. We can rewrite the definition of the derivative in Leibniz notation in the form

$$\frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x}$$

The following notations for the value of the derivative of $y = f(x)$ evaluated at the number a are equivalent:

$$y'(a) = f'(a) = \frac{dy}{dx} \Big|_{x=a} = \left[\frac{dy}{dx} \right]_{x=a}$$

Differentiable Functions

Definition 2.2.2. A function f is **differentiable at a** if $f'(a)$ exists. It is **differentiable on an open interval** (a, b) (or (a, ∞) or $(-\infty, a)$ or $(-\infty, \infty)$) if it is differentiable at every number in the interval.

Theorem 2.2.1. If f is differentiable at a , then f is continuous at a .

Proof. To prove that f is continuous at a , we want to show that

$$\lim_{x \rightarrow a} f(x) = f(a)$$

Given that f is differentiable at a so

$$f'(a) = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}$$

exists. Then

$$\lim_{x \rightarrow a} [f(x) - f(a)] = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} (x - a) = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} \cdot \lim_{x \rightarrow a} (x - a) = f'(a) \cdot 0 = 0$$

and

$$\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} [f(a) + (f(x) - f(a))] = \lim_{x \rightarrow a} f(a) + \lim_{x \rightarrow a} (f(x) - f(a)) = f(a) + 0 = f(a)$$

Therefore f is continuous at a . ■

Note that there are functions that are continuous but not differentiable. The function $y = |x|$ is continuous at 0 but it is not differentiable at 0. Since

$$f'(0) = \lim_{h \rightarrow 0} \frac{|0 + h| - |0|}{h}$$

if the limit exists. But

$$\begin{aligned} \lim_{h \rightarrow 0^-} \frac{|0 + h| - |0|}{h} &= \lim_{h \rightarrow 0^-} \frac{|h|}{h} = \lim_{h \rightarrow 0^-} \frac{-h}{h} = -1 \\ \lim_{h \rightarrow 0^+} \frac{|0 + h| - |0|}{h} &= \lim_{h \rightarrow 0^+} \frac{|h|}{h} = \lim_{h \rightarrow 0^+} \frac{h}{h} = 1 \end{aligned}$$

then the limit does not exist so $f'(0)$ does not exist. Thus $y = |x|$ is differentiable at all x except 0.

Higher Order Derivatives

If $y = f(x)$ is a differentiable function and its derivative $y' = f'(x)$ is also a differentiable function, then the **second derivative** of $y = f(x)$ is

$$y'' = f''(x) = \frac{d}{dx} \left(\frac{dy}{dx} \right) = \frac{d^2 y}{dx^2}$$

$f''(x)$ is the slope of the curve $y = f'(x)$ at the point $(x, f'(x))$, which is the rate of change of the slope of the original curve $y = f(x)$. In general, the second derivative is the rate of change of the rate of change. If $s = s(t)$ is the position function of an object, then its first derivative is the velocity $v(t)$ of the object as a function of time t :

$$v(t) = s'(t) = \frac{ds}{dt}$$

The instantaneous rate of change of velocity with respect to time is called the **acceleration** $a(t)$ of the object. Thus the acceleration function is the derivative of the velocity function and is therefore the second derivative of the position function:

$$a(t) = v'(t) = \frac{dv}{dt} = s''(t) = \frac{d^2s}{dt^2}$$

In general, the n th derivative of f is obtained from f by differentiating n times. If $y = f(x)$, we write

$$y^{(n)} = f^{(n)}(x) = \frac{d^n y}{dx^n}$$

Problem 2.2.2. Find the first and the second derivatives of $f(x) = x^3$.

Solution. The first derivative is

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{(x+h)^3 - x^3}{h} = \lim_{h \rightarrow 0} \frac{x^3 + 3x^2h + 3xh^2 + h^3 - x^3}{h} = \lim_{h \rightarrow 0} \frac{3x^2h + 3xh^2 + h^3}{h} \\ &= \lim_{h \rightarrow 0} (3x^2 + 3xh + h^2) = 3x^2 \end{aligned}$$

The second derivative is

$$\begin{aligned} f''(x) &= \lim_{h \rightarrow 0} \frac{3(x+h)^2 - 3x^2}{h} = \lim_{h \rightarrow 0} \frac{3(x^2 + 2hx + h^2) - 3x^2}{h} = \lim_{h \rightarrow 0} \frac{3x^2 + 6hx + 3h^2 - 3x^2}{h} \\ &= \lim_{h \rightarrow 0} \frac{6hx + 3h^2}{h} = \lim_{h \rightarrow 0} (6x + 3h) = 6x \end{aligned}$$

■

2.3 Basic Differentiation Formulas

The derivative of the constant function $f(x) = c$ is

$$\frac{d}{dx}(c) = 0$$

Proof. If $f(x) = c$ where c is a constant, then

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{c - c}{h} = \lim_{h \rightarrow 0} 0 = 0$$

■

Power Functions

$$\frac{d}{dx}(x) = 1$$

Proof. If $f(x) = x$, then

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{x+h-x}{h} = \lim_{h \rightarrow 0} \frac{h}{h} = \lim_{h \rightarrow 0} 1 = 1$$

■

The power rule: If n is a positive integer, then

$$\frac{d}{dx}(x^n) = nx^{n-1}$$

Proof. Let $f(x) = x^n$, then

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{(x+h)^n - x^n}{h}$$

We use the binomial theorem to expand $(x+h)^n$ then

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{\left(x^n + nx^{n-1}h + \frac{n(n-1)}{2}x^{n-2}h^2 + \dots + nxh^{n-1} + h^n \right) - x^n}{h} \\ &= \lim_{h \rightarrow 0} \frac{nx^{n-1}h + \frac{n(n-1)}{2}x^{n-2}h^2 + \dots + nxh^{n-1} + h^n}{h} \\ &= \lim_{h \rightarrow 0} (nx^{n-1} + \frac{n(n-1)}{2}x^{n-2}h + \dots + nxh^{n-2} + h^{n-1}) \\ &= nx^{n-1} \end{aligned}$$

because every term except the first has h as a factor and therefore approaches 0. ■

The power rule (general version): If n is any real number, then

$$\frac{d}{dx}(x^n) = nx^{n-1}$$

Problem 2.3.1. Differentiate $f(x) = 1/x$.

Solution.

$$\frac{d}{dx} \left(\frac{1}{x} \right) = \frac{d}{dx} x^{-1} = (-1)x^{-1-1} = -x^{-2} = -\frac{1}{x^2}$$

■

The **normal line** to a curve C at a point P is the line through P that is perpendicular to the tangent line at P . The constant multiple rule: If c is a constant and f is a differentiable function, then

$$\frac{d}{dx}[cf(x)] = c \frac{d}{dx}f(x)$$

Proof. Let $g(x) = cf(x)$. Then

$$\begin{aligned} g'(x) &= \lim_{h \rightarrow 0} \frac{cf(x+h) - cf(x)}{h} = \lim_{h \rightarrow 0} c \left(\frac{f(x+h) - f(x)}{h} \right) \\ &= c \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = c \frac{d}{dx} f(x) \end{aligned}$$

■

The sum rule: If f and g are both differentiable, then

$$\frac{d}{dx}[f(x) + g(x)] = \frac{d}{dx}f(x) + \frac{d}{dx}g(x)$$

Proof. Let $F(x) = f(x) + g(x)$. Then

$$\begin{aligned} F'(x) &= \lim_{h \rightarrow 0} \frac{[f(x+h) + g(x+h)] - [f(x) + g(x)]}{h} \\ &= \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} + \frac{g(x+h) - g(x)}{h} \right] \\ &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} + \lim_{h \rightarrow 0} \frac{g(x+h) - g(x)}{h} \\ &= \frac{d}{dx}f(x) + \frac{d}{dx}g(x) \end{aligned}$$

■

The sum rule can be extended to the sum of any number of functions. By writing $f - g$ as $f + (-1)g$ and applying the sum rule and the constant multiple rule, we get the following formula. The difference rule: If f and g are both differentiable, then

$$\frac{d}{dx}[f(x) - g(x)] = \frac{d}{dx}f(x) - \frac{d}{dx}g(x)$$

Proof. Let $F(x) = f(x) - g(x)$. Then

$$\begin{aligned} F'(x) &= \lim_{h \rightarrow 0} \frac{[f(x+h) - g(x+h)] - [f(x) - g(x)]}{h} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x) - g(x+h) + g(x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x) - [g(x+h) - g(x)]}{h} \\ &= \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} - \frac{g(x+h) - g(x)}{h} \right] \\ &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} - \lim_{h \rightarrow 0} \frac{g(x+h) - g(x)}{h} \\ &= \frac{d}{dx}f(x) - \frac{d}{dx}g(x) \end{aligned}$$

■

The Constant Multiple Rule, the Sum Rule, and the Difference Rule can be combined with the Power Rule to differentiate any polynomial.

The Sine and Cosine Functions

$$\frac{d}{dx}(\sin x) = \cos x$$

Proof. If $f(x) = \sin x$, then

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\sin(x+h) - \sin x}{h} = \lim_{h \rightarrow 0} \frac{\sin x \cos h + \cos x \sin h - \sin x}{h} \\ &= \lim_{h \rightarrow 0} \left[\frac{\sin x \cos h - \sin x}{h} + \frac{\cos x \sin h}{h} \right] = \lim_{h \rightarrow 0} \left[\sin x \left(\frac{\cos h - 1}{h} \right) + \cos x \left(\frac{\sin h}{h} \right) \right] \\ &= \sin x \cdot \lim_{h \rightarrow 0} \left(\frac{\cos h - 1}{h} \right) + \cos x \cdot \lim_{h \rightarrow 0} \left(\frac{\sin h}{h} \right) \\ &= (\sin x) \cdot 0 + (\cos x) \cdot 1 = \cos x \end{aligned}$$

■

$$\frac{d}{dx}(\cos x) = -\sin x$$

Proof. If $f(x) = \cos x$, then

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\cos(x+h) - \cos x}{h} = \lim_{h \rightarrow 0} \frac{\cos x \cos h - \sin x \sin h - \cos x}{h} \\ &= \lim_{h \rightarrow 0} \left[\frac{\cos x \cos h - \cos x}{h} - \frac{\sin x \sin h}{h} \right] = \lim_{h \rightarrow 0} \left[\cos x \left(\frac{\cos h - 1}{h} \right) - \sin x \left(\frac{\sin h}{h} \right) \right] \\ &= \cos x \cdot \lim_{h \rightarrow 0} \left(\frac{\cos h - 1}{h} \right) - \sin x \cdot \lim_{h \rightarrow 0} \left(\frac{\sin h}{h} \right) \\ &= (\cos x) \cdot 0 - (\sin x) \cdot 1 = -\sin x \end{aligned}$$

■

If $f(x) = \sin x$, then

$$f'(x) = \cos x \quad f''(x) = -\sin x \quad f'''(x) = -\cos x \quad f^{(4)}(x) = \sin x$$

In general, if $f(x) = \sin x$, then for $n = 0, 1, 2, \dots$ we have

$$f^{(4n)}(x) = \sin x \quad f^{(4n+1)}(x) = \cos x \quad f^{(4n+2)}(x) = -\sin x \quad f^{(4n+3)}(x) = -\cos x$$

If $f(x) = \cos x$, then

$$f'(x) = -\sin x \quad f''(x) = -\cos x \quad f'''(x) = \sin x \quad f^{(4)}(x) = \cos x$$

In general, if $f(x) = \cos x$, then for $n = 0, 1, 2, \dots$ we have

$$f^{(4n)}(x) = \cos x \quad f^{(4n+1)}(x) = -\sin x \quad f^{(4n+2)}(x) = -\cos x \quad f^{(4n+3)}(x) = \sin x$$

2.4 The Product and Quotient Rules

The Product Rule

The Product Rule: If f and g are both differentiable, then

$$\frac{d}{dx}[f(x)g(x)] = \left[\frac{d}{dx}[f(x)] \right] g(x) + f(x) \frac{d}{dx}[g(x)]$$

Proof. Let $F(x) = f(x)g(x)$. Then

$$\begin{aligned} F'(x) &= \lim_{h \rightarrow 0} \frac{F(x+h) - F(x)}{h} = \lim_{h \rightarrow 0} \frac{f(x+h)g(x+h) - f(x)g(x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x+h) - f(x)g(x) + f(x+h)g(x) - f(x+h)g(x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x) - f(x)g(x) + f(x+h)g(x+h) - f(x+h)g(x)}{h} \\ &= \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} g(x) + f(x+h) \frac{g(x+h) - g(x)}{h} \right] \\ &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} \cdot \lim_{h \rightarrow 0} g(x) + \lim_{h \rightarrow 0} f(x+h) \lim_{h \rightarrow 0} \frac{g(x+h) - g(x)}{h} \\ &= f'(x)g(x) + f(x)g'(x) \end{aligned}$$

■

The Quotient Rule

The Quotient Rule: If f and g are both differentiable, then

$$\frac{d}{dx} \left[\frac{f(x)}{g(x)} \right] = \frac{\left[\frac{d}{dx}[f(x)] \right] g(x) - f(x) \frac{d}{dx}[g(x)]}{[g(x)]^2}$$

Proof. Let $F(x) = \frac{f(x)}{g(x)}$. Then

$$\begin{aligned} F'(x) &= \lim_{h \rightarrow 0} \frac{F(x+h) - F(x)}{h} = \lim_{h \rightarrow 0} \frac{\frac{f(x+h)}{g(x+h)} - \frac{f(x)}{g(x)}}{h} = \lim_{h \rightarrow 0} \frac{f(x+h)g(x) - f(x)g(x+h)}{hg(x+h)g(x)} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x) - f(x)g(x+h) + f(x)g(x) - f(x)g(x)}{hg(x+h)g(x)} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x) - f(x)g(x) - f(x)g(x+h) + f(x)g(x)}{hg(x+h)g(x)} \\ &= \lim_{h \rightarrow 0} \frac{f(x+h)g(x) - f(x)g(x) - [f(x)g(x+h) - f(x)g(x)]}{hg(x+h)g(x)} \end{aligned}$$

$$\begin{aligned}
&= \lim_{h \rightarrow 0} \frac{\frac{f(x+h) - f(x)}{h} g(x) - f(x) \frac{g(x+h) - g(x)}{h}}{g(x+h)g(x)} \\
&= \frac{\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} \cdot \lim_{h \rightarrow 0} g(x) - \lim_{h \rightarrow 0} f(x) \cdot \lim_{h \rightarrow 0} \frac{g(x+h) - g(x)}{h}}{\lim_{h \rightarrow 0} g(x+h) \cdot \lim_{h \rightarrow 0} g(x)} \\
&= \frac{f'(x)g(x) - f(x)g'(x)}{[g(x)^2]}
\end{aligned}$$

■

Trigonometric Functions

$$\frac{d}{dx}(\tan x) = \sec^2 x$$

Proof.

$$\begin{aligned}
\frac{d}{dx}(\tan x) &= \frac{d}{dx} \left(\frac{\sin x}{\cos x} \right) = \frac{\left[\frac{d}{dx}(\sin x) \right] \cos x - \sin x \frac{d}{dx}(\cos x)}{\cos^2 x} \\
&= \frac{\cos x \cdot \cos x - \sin x(-\sin x)}{\cos^2 x} = \frac{\cos^2 x + \sin^2 x}{\cos^2 x} = \frac{1}{\cos^2 x} = \sec^2 x
\end{aligned}$$

■

$$\frac{d}{dx}(\csc x) = -\csc x \cot x$$

Proof.

$$\begin{aligned}
\frac{d}{dx}(\csc x) &= \frac{d}{dx} \left(\frac{1}{\sin x} \right) = \frac{\left[\frac{d}{dx}(1) \right] \sin x - 1 \cdot \frac{d}{dx}(\sin x)}{\sin^2 x} = \frac{0 \cdot \sin x - 1 \cdot \cos x}{\sin^2 x} \\
&= \frac{-\cos x}{\sin^2 x} = -\frac{1}{\sin x} \cdot \frac{\cos x}{\sin x} = -\csc x \cot x
\end{aligned}$$

■

$$\frac{d}{dx}(\sec x) = \sec x \tan x$$

Proof.

$$\begin{aligned}
\frac{d}{dx}(\sec x) &= \frac{d}{dx} \left(\frac{1}{\cos x} \right) = \frac{\left[\frac{d}{dx}(1) \right] \cos x - 1 \cdot \frac{d}{dx}(\cos x)}{\cos^2 x} = \frac{0 \cdot \cos x - 1 \cdot (-\sin x)}{\cos^2 x} \\
&= \frac{\sin x}{\cos^2 x} = \frac{1}{\cos x} \cdot \frac{\sin x}{\cos x} = \sec x \tan x
\end{aligned}$$

■

$$\frac{d}{dx}(\cot x) = -\csc^2 x$$

Proof.

$$\begin{aligned}\frac{d}{dx}(\cot x) &= \frac{d}{dx} \left(\frac{\cos x}{\sin x} \right) = \frac{\left[\frac{d}{dx}(\cos x) \right] \sin x - \cos x \frac{d}{dx}(\sin x)}{\sin^2 x} \\ &= \frac{(-\sin x) \cdot \sin x - \cos x \cdot \cos x}{\sin^2 x} = \frac{-\sin^2 x - \cos^2 x}{\sin^2 x} \\ &= \frac{-(\sin^2 x + \cos^2 x)}{\sin^2 x} = -\frac{1}{\sin^2 x} = -\csc^2 x\end{aligned}$$

■

2.5 The Chain Rule

The Chain Rule: If f and g are both differentiable and $F = f \circ g$ is the composite function defined by $F(x) = f(g(x))$, then F is differentiable and F' is given by the product

$$F'(x) = f'(g(x)) \cdot g'(x)$$

In Leibniz notation, if $y = f(u)$ and $u = g(x)$ are both differentiable functions, then

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$$

Comments on the proof of the Chain Rule: Let Δu be the change in u corresponding to a change of Δx in x , that is,

$$\Delta u = g(x + \Delta x) - g(x)$$

Then the corresponding change in y is

$$\Delta y = f(u + \Delta u) - f(u)$$

It is tempting to write

$$\begin{aligned}\frac{dy}{dx} &= \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta u} \cdot \frac{\Delta u}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta u} \cdot \lim_{\Delta x \rightarrow 0} \frac{\Delta u}{\Delta x} \\ &= \lim_{\Delta u \rightarrow 0} \frac{\Delta y}{\Delta u} \cdot \lim_{\Delta x \rightarrow 0} \frac{\Delta u}{\Delta x} = \frac{dy}{du} \cdot \frac{du}{dx}\end{aligned}$$

Note that $\Delta u \rightarrow 0$ as $\Delta x \rightarrow 0$ since g is continuous. The only flaw in this reasoning is that it might happen that $\Delta u = 0$ (even when $\Delta x \neq 0$) and, of course, we cannot divide by 0. Nonetheless, this reasoning does at least suggest that the Chain Rule is true. Note that dy/dx is the derivative of y with respect to x , whereas dy/du is the derivative of y with respect to u . The Power Rule combined with the Chain Rule: If n is any real number and $u = g(x)$ is differentiable, then

$$\frac{d}{dx}(u^n) = nu^{n-1} \frac{du}{dx}$$

Alternatively,

$$\frac{d}{dx}[g(x)]^n = n[g(x)]^{n-1} \cdot g'(x)$$

Suppose that $y = f(u)$, $u = g(x)$, and $x = h(t)$ where f, g, h are differentiable functions. Then, to compute the derivative of y with respect to t , we use the Chain Rule twice:

$$\frac{dy}{dt} = \frac{dy}{dx} \cdot \frac{dx}{dt} = \frac{dy}{du} \cdot \frac{du}{dx} \cdot \frac{dx}{dt}$$

Proof of the Chain Rule

If we denote ε the difference between the difference quotient and the derivative, we obtain

$$\lim_{\Delta x \rightarrow 0} \varepsilon = \lim_{\Delta x \rightarrow 0} \left(\frac{\Delta y}{\Delta x} - f'(a) \right) = f'(a) - f'(a) = 0$$

But

$$\varepsilon = \frac{\Delta y}{\Delta x} - f'(a) \implies \Delta y = f'(a)\Delta x + \varepsilon\Delta x$$

If we define ε to be 0 when $\Delta x = 0$, then ε becomes a continuous function of Δx . Thus, for a differentiable function f , we can write

$$\Delta y = f'(a)\Delta x + \varepsilon\Delta x$$

where $\varepsilon \rightarrow 0$ as $\Delta x \rightarrow 0$ and ε is a continuous function of Δx . The proof of the Chain Rule:

Proof. Suppose $u = g(x)$ is differentiable at a and $y = f(u)$ is differentiable at $b = g(a)$. If Δx is an increment in x and Δu and Δy are the corresponding increments in u and y , then we can write

$$\Delta u = g'(a)\Delta x + \varepsilon_1\Delta x = [g'(a) + \varepsilon_1]\Delta x$$

where $\varepsilon_1 \rightarrow 0$ as $\Delta x \rightarrow 0$. Similarly,

$$\Delta y = f'(b) + \varepsilon_2\Delta u = [f'(b) + \varepsilon_2]\Delta u$$

where $\varepsilon_2 \rightarrow 0$ as $\Delta u \rightarrow 0$. If we now substitute the expression for Δu , we get

$$\Delta y = [f'(b) + \varepsilon_2][g'(a) + \varepsilon_1]\Delta x$$

so

$$\frac{\Delta y}{\Delta x} = [f'(b) + \varepsilon_2][g'(a) + \varepsilon_1]$$

As $\Delta x \rightarrow 0$, it shows that $\Delta u \rightarrow 0$. So both $\varepsilon_1 \rightarrow 0$ and $\varepsilon_2 \rightarrow 0$ as $\Delta x \rightarrow 0$. Therefore

$$\frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \rightarrow 0} [f'(b) + \varepsilon_2][g'(a) + \varepsilon_1] = f'(b)g'(a) = f'(g(a))g'(a)$$

This proves the Chain Rule. ■

2.6 Implicit Differentiation

An explicit function $y = f(x)$ is defined by expressing one variable explicitly in terms of another variable. Some functions are defined implicitly by a relation between x and y . For example, the equation of the circle is defined by $x^2 + y^2 = r^2$ where the radius r is a constant. In some cases it is possible to solve an implicit function to get an explicit function. We can use the method of **implicit differentiation** to find the derivative of y . This consists of differentiating both sides of the equation with respect to x and then solving the resulting equation for y' .

Problem 2.6.1. Find dy/dx of the unit circle $x^2 + y^2 = 1$.

Solution. We differentiate on both sides of the equation then we have

$$\begin{aligned}\frac{d}{dx}(x^2 + y^2) &= \frac{d}{dx}(1) \\ \frac{d}{dx}(x^2) + \frac{d}{dx}(y^2) &= 0\end{aligned}$$

Since $y = f(x)$, we use the chain rule then we have

$$\begin{aligned}2x + \frac{d}{dy}(y^2) \frac{dy}{dx} &= 0 \\ 2x + 2y \frac{dy}{dx} &= 0\end{aligned}$$

We solve this equation for dy/dx :

$$\frac{dy}{dx} = -\frac{x}{y}$$

■

Problem 2.6.2. Find dy/dx of the folium of Descartes $x^3 + y^3 = 6xy$.

Solution.

$$\begin{aligned}x^3 + y^3 &= 6xy \\ \frac{d}{dx}x^3 + \frac{d}{dy}y^3 \left(\frac{dy}{dx} \right) &= \left[\frac{d}{dx}(6x) \right] y + 6x \frac{dy}{dx} \\ 3x^2 + 3y^2 \frac{dy}{dx} &= 6y + 6x \frac{dy}{dx} \\ x^2 + y^2 \frac{dy}{dx} &= 2y + 2x \frac{dy}{dx} \\ (y^2 - 2x) \frac{dy}{dx} &= 2y - x^2 \\ \frac{dy}{dx} &= \frac{2y - x^2}{y^2 - 2x}\end{aligned}$$

■

Problem 2.6.3. Find y' if $\sin(x + y) = y^2 \cos x$.

Solution.

$$\begin{aligned}\sin(x + y) &= y^2 \cos x \\ \cos(x + y)\left(1 + \frac{dy}{dx}\right) &= 2y \frac{dy}{dx} \cos x - y^2 \sin x \\ [2y \cos x - \cos(x + y)] \frac{dy}{dx} &= \cos(x + y) + y^2 \sin x \\ \frac{dy}{dx} &= \frac{\cos(x + y) + y^2 \sin x}{2y \cos x - \cos(x + y)}\end{aligned}$$

■

Problem 2.6.4. Find y'' if $x^4 + y^4 = 16$.

Solution. First we find y' then we have

$$\begin{aligned}x^4 + y^4 &= 16 \\ 4x^3 + 4y^3 \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{x^3}{y^3}\end{aligned}$$

Then we find y'' and we have

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{d}{dx} \left(-\frac{x^3}{y^3} \right) = -3x^2y^{-3} + (-x^3)(-3y^{-4}) \frac{dy}{dx} = 3x^3y^{-4}(-x^3y^{-3}) - 3x^2y^{-3} \\ &= -3x^6y^{-7} - 3x^2y^{-3} = -3x^2y^{-7}(x^4 + y^4) = -48 \frac{x^2}{y^7}\end{aligned}$$
